

Module Interfaces (TCP Fast Retransmit and Recovery)			
Client Node	Internet	Server Node	EventStudio System Designer 6

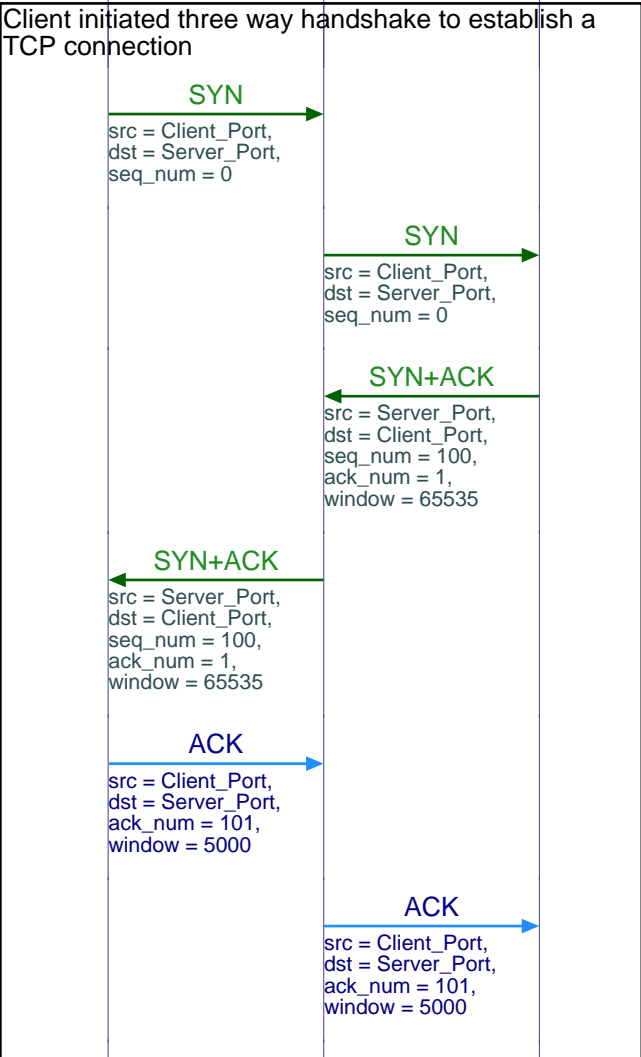

This sequence diagram was generated with EventStudio System Designer (<http://www.EventHelix.com/EventStudio>).

TCP Slow Start and Congestion Avoidance lower the data throughput drastically when segment loss is detected. Fast Retransmit and Fast Recovery have been designed to speed up the recovery of the connection, without compromising its congestion avoidance characteristics.

Fast Retransmit and Recovery detect a segment loss via duplicate acknowledgements. When a segment is lost, TCP at the receiver will keep sending ack segments indicating the next expected sequence number. This sequence number would correspond to the lost segment. If only one segment is lost, TCP will keep generating acks for the following segments. This will result in the transmitter getting duplicate acks (i.e. acks with the same ack sequence number)

Server awaits client socket connections.

Client sets the SYN bit in the TCP header to request a TCP connection. The sequence number field is set to 0. Since the SYN bit is set, this sequence number is used as the initial sequence number

SYN TCP segment is received by the server

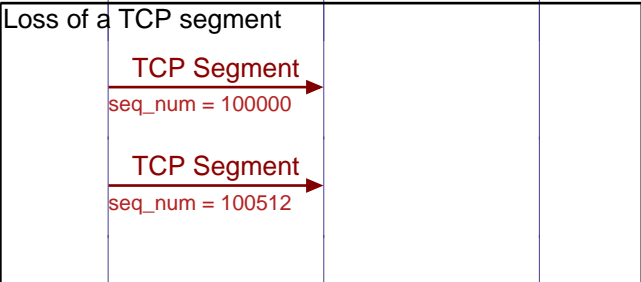

Server sets the SYN and the ACK bits in the TCP header. Server sends its initial sequence number as 100. Server also sets its window to 65535 bytes. i.e. Server has buffer space for 65535 bytes of data. Also note that the ack sequence number is set to 1. This signifies that the server expects a next byte sequence number of 1

Client receives the "SYN+ACK" TCP segment

Client now acknowledges the first segment, thus completing the three way handshake. The receive window is set to 5000. Ack sequence number is set to 101, this means that the next expected sequence number is 101.

Server receives the TCP ACK segment

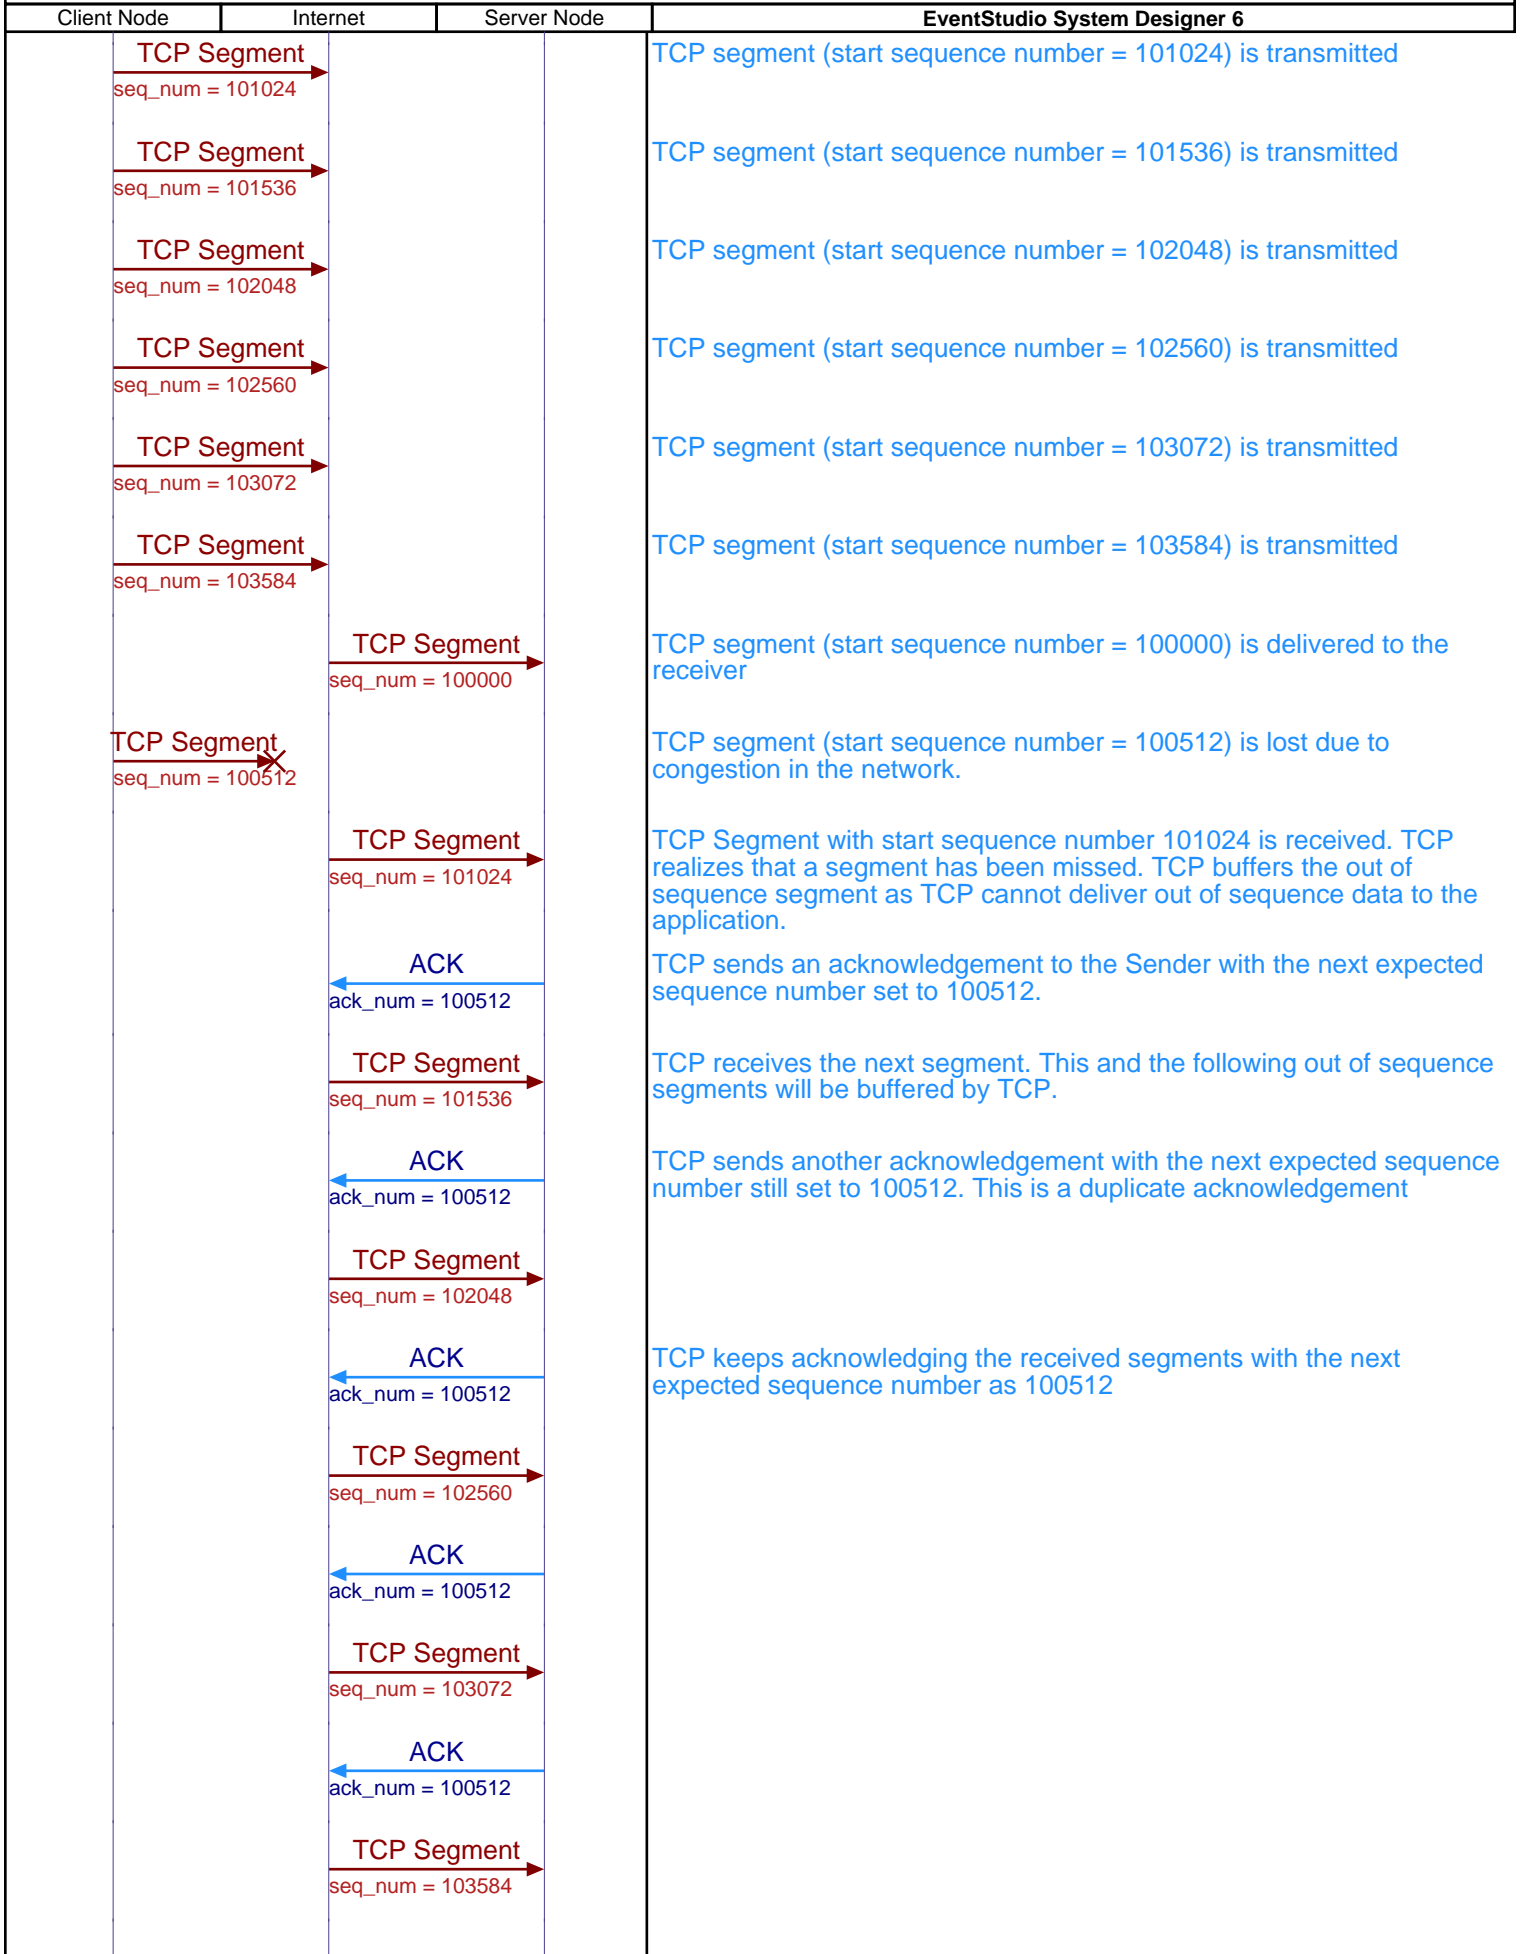

TCP Connection begins with slow start. The congestion window grows from an initial 512 bytes to 70000 bytes

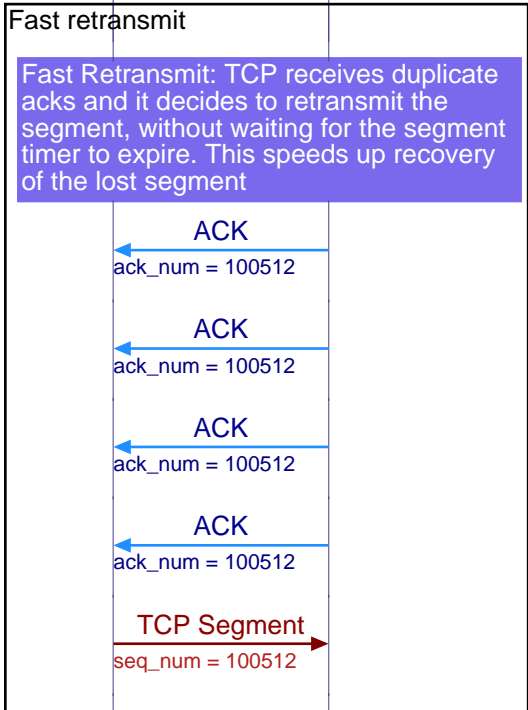

TCP segment (start sequence number = 100000) is transmitted

TCP segment (start sequence number = 100512) is transmitted

Module Interfaces (TCP Fast Retransmit and Recovery)

Module Interfaces (TCP Fast Retransmit and Recovery) EventStudio System Designer 6

Client receives acknowledgement to the segment with starting sequence number 100512

First duplicate ack is received. TCP does not know if this ack has been duplicated due to out of sequence delivery of segments or the duplicate ack is caused by lost segment.

Second duplicate ack is received

Third duplicate ack is received. TCP now assumes that duplicate acks point to a segment that has been lost

TCP retransmits the missing segment i.e. the segment corresponding to the ack sequence number in the duplicate acks

Another duplicate ack is received. This means that the receiver has buffered one more segment

Yet another ack is received, this will further inflate the congestion window

Finally, the retransmitted segment is delivered to the server

Now TCP acknowledges all the segments that it had buffered

The cumulative TCP ack is delivered to the client

Congestion Avoidance

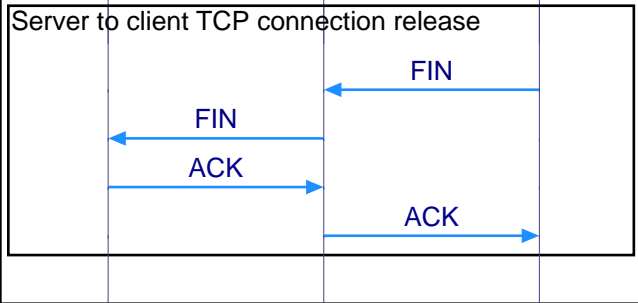

Client sends a TCP segment with the FIN bit set in the TCP header

Module Interfaces (TCP Fast Retransmit and Recovery)

Client Node Internet Server Node **EventStudio System Designer 6**

Server receives the FIN
Server responds back with ACK to acknowledge the FIN
Client receives the ACK

Server to client TCP connection release
FIN is sent out to the client to close the connection
Client receives FIN
Client sends ACK
Server receives the ACK
